For the purpose of the ISBI HARDI reconstruction challenge 2013 and for the category of DSI acquisitions we reconstructed the diffusion datasets using two methods: a) Generalized Q-sampling Imaging 2 [1], [2] with spherical deconvolution [3] (GQID), [?] and b) Diffusion Spectrum Imaging with Deconvolution [4] (DSID).

GQI2 provides a direct analytical formula to calculate the solid angle ODF ( $\psi_{GQI2}$ ) of DSI without the need of the diffusion propagator:

$$\psi_{GQI2}(\mathbf{u}) = \lambda^3 \int S(\mathbf{q}) H(2\pi\lambda\mathbf{q} \cdot \mathbf{u}) d\mathbf{q} \quad (1)$$

where  $\mathbf{u}$  is the unit direction in the sphere,  $\mathbf{q}$  is the q-space wave vector,  $S$  is the DW signal,  $\lambda$  is a smoothing parameter called the sampling length and  $H(x) = \begin{cases} 2 \cos(x)/x^2 + (x^2 - 2) \sin(x)/x^3, & x \neq 0 \\ 1/3, & x = 0 \end{cases}$

In [1] it was shown that  $\psi_{GQI2}$  creates ODFs with higher angular accuracy than standard DSI ODFs. In this work we further extended  $\psi_{GQI2}$  with the spherical deconvolution transform (SDT).

The SDT is a sharpening operation which transforms the smooth diffusion ODF into a sharper fiber ODF. The idea here is that an ODF for example the GQI2 ODF  $\psi_{GQI2}$  can be formed by convolution between the single fiber diffusion ODF kernel,  $R$  and the true fiber ODF  $\psi_{GQID}$

$$\psi_{GQI2}(\mathbf{u}) = \int_{|\mathbf{w}|=1} R(\mathbf{u} \cdot \mathbf{w}) \psi_{GQID}(\mathbf{w}) d\mathbf{w} \quad (2)$$

The deconvolution is a fast converging iterative process.

In order to deal with the high levels of noise, the diffusion weighted (DW) datasets for SNR 10 and 20 were denoised with adapted non-local means filtering [5] using a rician noise model. As proposed in [5], each DW images were processed independently. The DW dataset with SNR 30 was left intact and no further denoising was performed.

In GQI2 we usually use  $2 \leq \lambda \leq 3$  as higher values can give noisier ODFs as we see at Fig.1L. However, higher  $\lambda$  has the advantage that we are sampling from a higher radius in q-space (higher b-values) where most of the angular information lives. Using the GQID we show at Fig.1R that we can eliminate those noisy peaks and obtain sharper ODFs.

Apart from the GQID, for comparisons we also performed reconstructions using DSI with deconvolution [4]. This deconvolution is not a spherical one but it is performed in the 3D grid of the DSI propagator using Lucy-Richardson deconvolution. DSID creates very sharp ODFs as shown in Fig.2.

In order to find the best parameters for the methods described here we created a connectivity matrix after generating deterministic streamlines from the ODFs of the training set. We finally selected the parameters which minimized the number of missing and false bundles in the training set and used those with the test data. The
